Detection of Chlamydia pneumoniae DNA in the kidney transplant recipients. Chlamydia pneumoniae causes persistent inflammation of transplanted kidneys and is a potential agent of acute tubular necrosis (ATN). C. pneumoniae infection can be diagnosed by culture, antigen tests, and nucleic acid amplification tests. This study aimed to determine whether C. pneumoniae infection is involved in the pathogenesis of ATN in kidney transplant recipients (KTRs) using nested polymerase chain reaction (nPCR) for detection of C. pneumoniae genome. Forty-five KTRs and 30 controls were included. C. pneumoniae was detected in 25.6% of KTRs and 8.3% of controls. In KTRs, the prevalence of C. pneumoniae infection was significantly higher in those with donor-transmitted ATN (DATN) (37.5%) than in those without DATN (15.7%) ($p=0.007$). The incidence of post-transplant ATN in recipients with C. pneumoniae infection was significantly higher than that in recipients without C. pneumoniae infection ($p=0.003$). In DATN, C. pneumoniae was more frequently detected in ATN-positive KTRs than in ATN-negative KTRs ($p=0.013$). C. pneumoniae is not involved in the pathogenesis of ATN, but the prevalence of C. pneumoniae infection was significantly higher in ATN-positive KTRs than in ATN-negative KTRs.
