At the time of this writing, the current version is Photoshop CS6. Earlier versions are available through third-party software vendors. Photoshop is supplied as a stand-alone program in your computer's CD drive or online through Adobe, or it can be downloaded for free from the Adobe website. You can use Photoshop anywhere, but it does require a connection to an Internet or a high-speed Internet service. Photoshop is powered by the Adobe Creative Suite, which includes both Photoshop CS6 and the other Adobe Creative Suite programs, such as Illustrator, InDesign, and Muse. The Adobe Creative Suite also includes e-mail, text, web, and page-layout programs. Of course, Photoshop is only one of the many programs in the suite. Figure 1-1 gives you a close look at the Adobe Creative Suite. **Figure 1-1:** The Adobe Creative Suite. Before starting on your image editing adventures with Photoshop, you need to know a little about color. A color is really just a tiny mark placed on a spectrum by a light. The spectrum is what physicists call a surface on which light waves are reflected and refracted; it's a lot like a rainbow. The spectrum is formed by placing colored lights of various colors next to each other, which causes the different colors to reflect and refract off the colored light, giving the rainbow effect. Black and white (or grayscale) images have only one possible color, white. In grayscale images, white is the only color. There are many colors in the spectrum, and they're color-coded for you. Red is represented by the color from the spectrum known as `_red,_` and the code for red is called `red`. Similarly, orange is represented by the color from the spectrum known as `_orange,_` which is code for orange, as well. All the other colors in the spectrum are designated by codes that are assigned numbers, such as blue, which is known as `_cyan,_` and green, which is known as `_green,_` both of which are represented by the codes `green` and `blue`. Although the terms `_color_` and `_pixel_` (for small picture element) may sometimes get used interchangeably, they aren't really the same thing. Color consists of small color marks placed on the spectrum. The pixel is a square box inside of which the color marks reside.

At the University of California, Berkeley, we're learning how to make a quantum computer for the home and the classroom—one that can be built with highly distributed and specialized resources. It's important to make good use of parallelism, in every aspect of life and work. But we tend to think about parallelism as a kind of job for supercomputers, or at least for the kind of workload that used to be performed by them. But what is parallelism? We've been feeling silly about this issue in Berkeley since about the year 2000, when our Computer Science department decided to take its (excellent) computer science graduate program in parallel, meaning distributed, from the practice of computer science to distributed computing. But my confession is that at the department's first workshop on parallel computers, I was pretty clueless. My graduate program had little to say about parallelism; I'd never heard of Supercomputer X and had no idea why it could be so important to building a quantum computer. In a practical sense, I couldn't imagine doing science, say, with lots of remote computers—but that just made the idea of parallelism even fuzzier in my mind. And then I was moved to Berkeley. The issue of parallelism is an important one for us here, for a few reasons. First, we need to push the boundaries of what's possible with a supercomputer to think about how to make quantum computers for the home. Second, there's the fact that by the end of this decade, your typical desktop computer will be connected in a big distributed network, so we need to think about ways to use that network when it's on, rather than just like something to download your computer with. And, third, it's an important part of the explanation of how the multiprocessor machines we all have in our homes can be used for more than just high-end games. To explain it a bit, in the context of information technology and statistics, the idea of parallelism has many meanings. Here's the basic idea: in the future, we'll have many computers working in the background, and maybe even all of them working in the background, without being necessarily specifically aware that they're participating in some kind of parallel processing. Maybe many of us in the room will be

The present invention relates to an apparatus and method for replicating and transporting records and more particularly to a versatile, efficient, easy to use, and low cost apparatus and method for reproducing and transporting a plurality of records formed by different media. In the reproduction of records on record media, it is desired to produce replicas which are duplicates of the original record on the record media with as high a degree of accuracy and consistency as possible. The technique used to reproduce records, therefore, should preferably not cause any physical damage to the record medium. In fact, the record medium should be scrupulously handled to avoid any possibility of smearing, etc. Because of this, very expensive and complex apparatus and methods have been used to reproduce records formed on mediums such as metallic master records. The most common means of reproducing or duplicating records in the commercial field today is to place a master record on a turntable, connect a phonograph needle to a high voltage system and drive the turntable. As the needle travels along the record track, a stylus also connected to the high voltage system works its way along the record surface, imitating, at the speed of the turntable, the sound of the record through the needle and stylus. This method, of course, is expensive and requires a great deal of maintenance. Since a record contains a significant amount of information, it is required to obtain and maintain a high degree of accuracy in the reproduction of the record. This accurate reproduction requires the use of extremely expensive and high degree of precision components. Records are used in a wide variety of different applications. For example, a record can be used to identify and classify the contents of a container. Each container is uniquely identified by a master record in which certain data is inscribed. For example, the container could contain a series of numerical digits which indicate the serial numbers of containers in a supply chain. The content of the container, therefore, would be identified by the numbers in the master record and the container could be monitored as it moves along the supply chain. The information contained in the master record could also indicate certain conditions to occur once the container reaches its destination, for example, an error in the container or a shipment error. Another application for master records is to indicate the plant of origin of a container after it has been opened. In this application, the track in which the record is formed will identify the plant of origin. The contents of the container may then be indicative of the source of the contents.
